- 0. The Dean has instructed us to give no clarifications during the course of the exam to prevent students from being disturbed. If you have a clarifications during the course of the exam to prevent students are prevent the question to the from being disturbed. If you have any doubts, please state your assumptions and answer the question to the
- 1. Write your answers on the printed question paper in the space provided. ROUGH SHEETS WILL NOT BE COLLECTED NOT BE COLLECTED.
- 2. Please write your name on every page and enter your serial number in the box above. If you miss out any of these: -1 and no rechastion
- 3. No pseudocode means: For every loop you use, you must explain what it will do to the input. You cannot write "for write things like "x - x + y", you must explain the significance of every step in words. You cannot write "for I to ..." or "while <condition>...", you must explain what the loop achieves. In summary: if we need to interpret how your description will treat a particular input then it is pseudocode.

Q1. Short answer questions (Total marks = 11)

Marks:

Q1.1 (2 marks) Consider the 2-4 tree given in Figure 1.

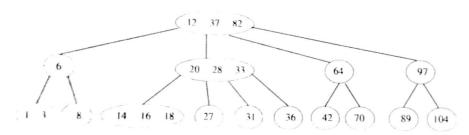

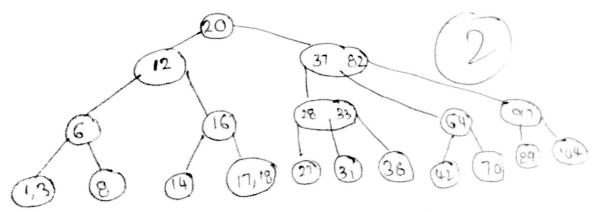

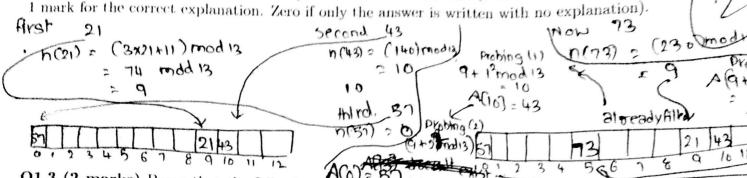

Figure 1: A 2-4 tree

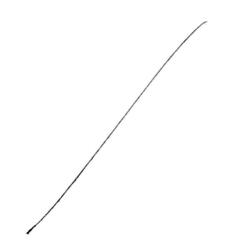

Draw the state of the tree after inserting 17. You do not have to show the intermediate steps, only the final answer

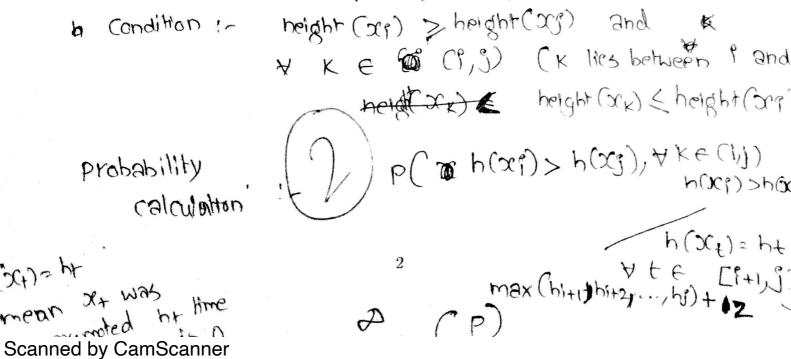

Q1.2 (2 marks) Consider open addressing with quadratic probing i.e. if the hashtable A has size n and the hash function is $h(\cdot)$, then if we have to insert x and if the location $A[h(x) \mod n]$ is occupied, we try $A[h(x) + 1^2 \mod n]$, $A[h(x) + 2^2 \mod n]$, $A[h(x) + 3^2 \mod n]$, etc in sequence till we find an empty slot and insert x there. Consider a hashtable of size 13 and the hash function $h(x) = (3x + 11) \mod 13$. Assume that 21, 43 and 57 are already inserted into this hashtable. Where will 73 be inserted? To get full marks you must explain how you arrived at the answer. (1 mark for the correct answer and 1 mark for the correct answer and

Q1.3 (2 marks) Prove that the following statement is false: It is not possible to make an AVL tree on 10 or more nodes such that the left subtree of the root contains less than one third of the nodes that the right subtree contains.

Q1.4 (3 marks) Consider a probabilistic skip list with parameter p (i.e. a key in S_i is selected for S_{i+1} with probability p) containing the elements x_1, x_2, \ldots, x_n numbered in ascending order (i.e. the order in which they appear in the base list S_0). Consider two elements x_i and x_j such that i < j. Under what condition (on the heights of the various elements in the skip list) is it true that the search path to x_j will go through x_i ? What is the probability that the search path to x_j goes through x_i ? (2 marks for the condition and 1 mark for the probability calculation).

turns and some right turns. On the binary search tree can be written as a sequence of turns, some left and so on. I turns and some right turns, e.g., if the root has key 12 and we are searching for 26, the first turn is Right be the this sequence of t this sequence of t the root has key 12 and we are searching for 26, the first turn is Right be the this sequence of t. and so on. Let this sequence of turns be t_1, t_2, \ldots, t_k (each t_i is either L or R) and let x_1, x_2, \ldots, x_k turns and which the turns be t_1, t_2, \ldots, t_k (each t_i is either L or R). If t_i and t_j are both left be the the nodes at which the turns were taken (e.g. x_1 is always the root). If t_i and t_j are both left turns, under what condition is turns, under what condition is $x_j > x_i$?

A) has key SN is given both to and the arc woode we are searching for is less than woode we are searching both the other a during traversal 11. both the given N lett turns turns, The Mode we all with key I is a child of I child of I chince BST traversal path goes in this way)

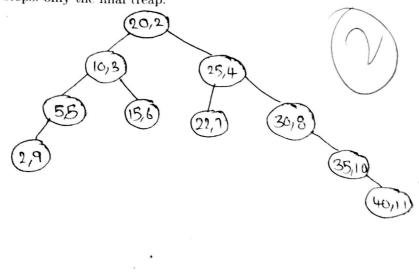

as to left to Mode (I) is in the left subtree of the control of t , The X9 < X1

Q2. (Tree + heap = Treap. Total marks = 9). Marks: 8 A Treap is a special kind of binary search tree which also has the property of a heap. Each item in a treap is a tuple of two and treap is a binary treap is a tuple of two values i.e. $x_i = (k_i, p_i)$ where k_i is a key and p_i is a priority. A treap is a binary search tree on the house $x_i = (k_i, p_i)$ where k_i is a key and p_i is a priority on the priorities i.e. search tree on the keys of the items and maintains the min-heap order property on the priorities i.e. the priority value of $x_i = (k_i, p_i)$ where k_i is a key and p_i is a priority. Note that the the priority value of a node is less than the priority value of any children it may have. Note that the Treap does not have to have the structural property of a heap i.e., it may not be a complete binary tree but must have the order property of a heap.

Q2.1 (2 marks). Construct a Treap on the set

$$S = \{(22,7), (20,2), (2,9), (10,3), (35,10), (40,11), (15,6), (30,8), (25,4), (5,5)\}.$$

You do not need to show the steps, only the final treap.

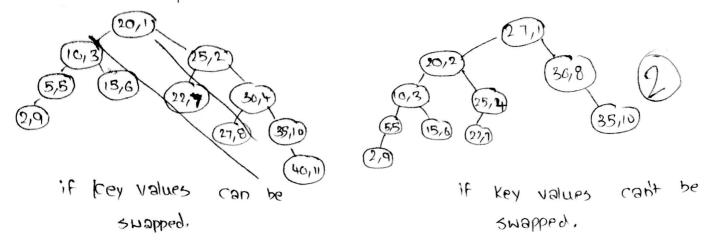

Q2.2 (2 marks). In the Treap constructed in the previous part insert (27,1). The insertion algorithm proceeds by first inserting the node in its appropriate place as a binary search tree node and then adjusting the key correctly. Draw the heap after the insertion has completed. (Use the space given

(Continued)) As it can be seen through rotations can be successfully converted to new as it new root. The rotations take continued the whole tree can't be corrected to a the whole tree can't be corrected to a Sub BS GLGLA hew sub treap with Constant Home, B treap in phas 9 then Should the IN becomes the new root so whole trop height is he

and

1ature

Q2.3 (5 marks) Explain the Treap insertion algorithm. As mentioned before you must begin by doing a BST insertion of the new (key, priority) pair and then adjust the priorities. Explain how this adjustment phase proceeds. Note: (1) **No pseudocode**. (2) You must justify your steps, i.e. argue the for the correctness of your algorithm. Without an argument of correctness you will get a maximum of 2 marks even for a perfectly correct answer. (3) Your insertion mechanism should work in O(h) time where h is the height of the Treap. (Hint: If the priorities and keys are all different, as they are in this case, then any set of keys gives a unique Treap, so in the previous part you can find the correct answer simply by constructing a Treap on $S \cup \{(27,1)\}$ from scratch. The purpose of the previous part is to help you figure out the adjustment phase of the insertion algorithm. Since you can tell the final answer by constructing the final Treap from scratch, you can check using this example if you are doing the adjustment phase correctly.)
